FOLDABLE ELECTRONIC DEVICE**CROSS REFERENCE TO RELATED APPLICATIONS**

This application is the U.S. National Stage of International Application Number PCT/IB04/003072 filed on Sep. 21, 2004 which was published in English on Mar. 30, 2006 under International Publication Number WO 2006/032938.

TECHNICAL FIELD

The invention relates to a foldable electronic device comprising a casing with a top cover and a base cover being pivotably connected to each other by means of a hinge, such that the top cover can be pivoted relative to the base cover between an opened position and a closed position, a display which is visible in the opened position of the casing and which is hidden inside the casing in the closed position of the casing and a keyboard with a plurality of keycaps.

BACKGROUND OF THE INVENTION

Various electronic devices, especially hand-held computing devices, have become popular as portable computers, personal organizers and as wireless communication devices due to their small size and portability.

These devices typically comprise a two-part casing having a top cover and a base cover, wherein a display is fixedly accommodated within the top cover and wherein a keyboard with a plurality of keycaps is fixedly accommodated within the base cover. The top cover with the integrated display is pivotably connected to the base cover with the integrated keyboard via a hinge. The top cover can be pivoted relative to the base cover between an opened position and a closed position, wherein in the closed position the top cover and the base cover are stacked together. When pivoting the top cover relative to the base cover to an opened position, the display and the keyboard which are arranged at the inner side of the casing become visible and the electronic device becomes operable. In the closed position of the casing both the display and the keyboard are surrounded by the casing so as to form a protecting jacket around the sensitive and damageable parts inside the casing, that is the keyboard and especially the display.

Since such electronic devices are often used as portable devices, the size, that is the length and the width, of the casing parts have to be reduced to a minimum. As a consequence, the display and the keyboard are small sized, too. Various devices are known from the state of the art which size and shape are such that they easily fit into pockets of clothing pieces, such as trouser pockets.

The problem of the known devices is that due to the relative small size of the display operation of the electronic device require increased attentiveness and concentration. Especially when browsing internet, writing documents, viewing photos or, in case of a navigation system, viewing road maps, the display of such electronic devices is inadequate in size.

SUMMARY OF THE INVENTION

It is an object of the invention to provide a foldable electronic device which is more comfortable to use and which does not require increased attentiveness and concentration when looking at the display.

According to one embodiment of the present invention a foldable electronic device as initially described is provided,

2

wherein the display comprises a first display portion and a second display portion, the first display portion being accommodated within or adjacent to the top cover of the casing and the second display portion being accommodated within or adjacent to the base cover of the casing, and wherein the first display portion forms the upper part of the display and the second display portion forms the lower part of the display.

In other words, a two-part display is provided which folds open, when the casing of the electronic device is opened so as to form a large common display consisting of a first (upper) display portion and a second (lower) display portion. Such an enlarged display is very comfortable especially when browsing internet, writing a document or viewing road maps, photos etc.

Since according to the present invention one of the first and second display portions is being arranged in the area in which according to the state of the art typically the keyboard is being arranged, according to a further embodiment of the present invention the keyboard is connected to the base cover and/or to the second display portion, wherein the keyboard is preferably accommodated within the base cover and/or the second display portion.

According to another embodiment of the present invention the connection between the keyboard and the base cover and/or the second display portion is a slideable connection, wherein the keyboard is arranged slideably relative to the base cover and/or the second display portion between a closed position and an opened position.

According to yet another embodiment of the present invention the keyboard is an out pullable keyboard, wherein in the closed position the keyboard is at least partly surrounded by the base cover and/or the second display portion. Preferably, in the closed position of the keyboard the plurality of keycaps is at least partly covered by the base cover and/or the second display portion. When the keyboard is pulled out it can be used for typing, and when the keyboard is in its closed position the keyboard and/or the plurality of keycaps is protected at least partly inside the casing of the electronic device.

According to a further embodiment of the present invention the connection between the keyboard and the base cover and/or the second display portion is a pivotable connection, wherein the keyboard is arranged pivotably relative to the base cover and/or the second display portion between an upper position and a lower position. Preferably, the keyboard is both slideable and pivotable, such that for example when pulling out the keyboard the keyboard slides out parallel to the base cover and/or the second display portion to the opened position and then the keyboard can be pivoted to a lower position which allows ergonomic positioning of the keyboard.

According to yet another embodiment of the present invention the first and second display portions are connected to each other via a hinge, wherein the first display portion is further connected hingedly to the top cover and wherein the second display portion is further connected hingedly to the base cover, wherein in the opened position of the casing the first and second display portions are at least partly folded out of the respective cover and wherein in the closed position of the casing the first and the second display portions are accommodated within and/or adjacent to the respective cover.

Alternatively, the first and second display portions, instead of being connected hingedly to each other and to the respective covers, are fixedly mounted to the respective cover, wherein in the opened position and in the closed position of the casing the first and second display portions are accommodated within and/or adjacent to the respective cover. This allows to fold out the first and second display portions in such
